Introduction

It is practically impossible to conduct long-term water quality measurements across an entire lake. To overcome this problem, simulation results can be used as measurements in the analysis of cross sectional salt flux. A three-dimensional hydrodynamic model is applied to study the dynamics of water and salt exchange through cross-sections. The model is validated with field data. Then the model results are used to study the characteristics of water and salt exchange [1]. The goals of this approach are to examine the mechanisms that drive water and salt transport in estuaries and coastal lakes, and how they are influenced by different forcing conditions. The approach can also be applied in the study of pollutants.

The Validation of the Model

The agreement between simulation results and observed data for the total, tidal and sub tidal components of the surface elevation and current velocity at several stations in the computational domain is important. The model needs to be checked if it has successfully reproduced response of surface elevation and current velocity to river discharge, atmospheric pressure and wind. The same validation process is done for the simulation results of salinity and pollutants.

The mean error (ME), mean absolute error (MAE), and predictive skill (Skill) are used as quantitative assessments for the comparison simulation results - observed data. They are defined as [1]:

$$ME = \frac{\sum (M_n - O_n)}{N} \quad (1)$$

$$MAE = \frac{\sum |M_n - O_n|}{N} \quad (2)$$

$$Skill = 1 - \frac{\sum (M_n - O_n)^2}{\sum (|M_n - \bar{O}| + |O_n - \bar{O}|)^2} \quad (3)$$

Where M_n and O_n are the n^{th} simulation result and observation, respectively, \bar{O} is the time mean data, and N is the number of observations. On average positive ME indicates over-prediction

and negative ME indicates under prediction. The average deviation between simulation results and observed data is indicated by the magnitude of MAE. Skill indicates the ability for the model to reproduce observed data; a skill of one indicates perfect agreement and zero indicates complete disagreement.

Salt Fluxes across a Vertical Cross Section

The equations originally derived by Hansen [2] are used in conducting the analysis of the processes governing the flux of materials along the longitudinal direction of an estuary or coastal lake [3]. Many studies have applied these equations to analyze of the longitudinal flux of materials [4-7].

The final simplified equation of the water flux (F_w) through the section, assuming turbulent fluctuations and tidal fluctuations are uncorrelated is

$$\langle F_w \rangle = \langle A \rangle \langle \bar{u} \rangle + \langle A_p \bar{u}_p \rangle + \langle A' \bar{u}' \rangle$$

$$\langle F_w \rangle = \langle A \rangle \langle \bar{u} \rangle + \langle A_p \bar{u}_p \rangle + \langle A' \bar{u}' \rangle \quad (4)$$

where u is longitudinal velocity, subscript p denotes the major harmonic variations, and primes denote turbulent fluctuations, the angle brackets denote mean values over the tidal period T and the bar denotes mean value of any variable over the cross section. The term $\langle A \bar{u} \rangle$ is the seaward water flux through the mean cross-sectional area (A) carried by the mean flow, usually referred to as the non-tidal drift. The flux $\langle A_p \bar{u}_p \rangle$ is due to tides and is generally landward. The turbulent flux, $\langle A' \bar{u}' \rangle$, represent water transport by motions of less than semidiurnal period, is generally negligible.

Instantaneous salt fluxes are a sum of cross sectional average and deviations there from. Assuming non-stationary conditions, the mean salt flux over a tidal cycle is

$$\langle f_s \rangle = \frac{1}{T} \int_0^T F_s(t) dt = \langle A \bar{u} \bar{s} \rangle + \langle A' \bar{u}' \bar{s}' \rangle \quad (5)$$

The cross-sectional salinity averages, and deviations from the mean salt flux can also be considered as the sum of a tidal mean, a tidal fluctuation and a turbulent fluctuation. The velocity,

salinity, mean deviation product of velocity and salinity, and cross-sectional area vary with time. The shear effect can be separated into lateral and vertical components [4,5]. Further, considering three dimensional profiles the deviations of velocity and salinity from the cross-sectional mean, can be separated into variations in the vertical transverse directions. Thus, the mean salt flux over a tidal cycle through a cross section is given by:

$$\begin{aligned} \langle F_s \rangle = & \frac{\langle A \rangle \langle \bar{u} \rangle \langle \bar{s} \rangle}{1} + \frac{\langle A_p \bar{u}_p \rangle \langle \bar{s} \rangle}{2} + \frac{\langle A_p \bar{s}_p \rangle \langle \bar{u} \rangle}{3} \\ & + \frac{\langle A \rangle \langle \bar{u}_p \bar{s}_p \rangle}{4} + \frac{\langle A_p \bar{u}_p \bar{s}_p \rangle}{5} + \frac{\langle A \rangle \langle \bar{u}_{dt} \rangle \langle \bar{s}_{dt} \rangle}{6} \\ & + \frac{\langle A \rangle \langle \bar{u}_{dv} \rangle \langle \bar{s}_{dv} \rangle}{7} + \frac{\langle A \rangle \langle \bar{u}_t \rangle \langle \bar{s}_t \rangle}{8} + \frac{\langle A \rangle \langle \bar{u}_v \bar{s}_v \rangle}{9} \quad (6) \\ & + \frac{\langle A_p \bar{u}_t \bar{s}_t \rangle}{10} + \frac{\langle A_p \bar{u}_v \bar{s}_v \rangle}{11} \end{aligned}$$

where the bars indicate cross-sectional averages and angle brackets indicate a time-average. Terms 1-5 quantify advection, and terms 6-11 quantify the shear effect associated with the variation in salinity and velocity within the cross section. Terms 1 and 2 provide the flux on the “non-tidal” drift. Terms 2-5 account for what is called “tidal pumping”, associated fluxes due to phase differences in the cross sectional averages of the tidal variations in velocity, salinity and cross sectional area [4]. Physical processes related with the terms of equation (6) are listed in Table 1.

Table 1: Physical processes related with the terms of equation (6).

Term	Physical Processes
1.	The flux associated with the river discharge
2.	The compensating flow for the inward transport on the partially progressive tidal wave, the stokes drift
3.	The correlation of tidal period variation of tidal height and salinity
4.	The correlation of tidal period variations of salinity and current
5.	The third order correlation of tidal period variations in salinity, velocity and cross-sectional area
6.	The contribution of the net transverse circulation
7.	The net vertical circulation
8.	The transverse oscillatory shear
9.	The vertical oscillatory shear

10.	The covariance of tidal fluctuations in cross-sectional area and the transverse oscillatory shear.
11.	The covariance of tidal fluctuations in cross-sectional area and the vertical oscillatory shear.

Discussion and Conclusion

A model study of the dynamics of water and salt exchange through cross-sections in Lakes Shinji and Nakaumi, Japan was done using the approach discussed here [7]. The hydrodynamic model in the STOC-LT (Ise Bay Simulator) was used [8]. The salinity simulation results were not quite in agreement with observed results (skill level of about 80%), however,

Interesting observations were made on the results of the mean salt flux over a tidal cycle through a cross section. Analysis over 1.5-year period reveals that the terms of equation (6) are not balanced. The results indicate an overall increase of salinity within Lake Shinji. The results also indicated that an increase in stratification produces an outflow of salt associated with the vertical tidal oscillatory shear. Huge river discharge suppresses vertical mean shear, and gravitational circulation diminishes, resulting in salt outflow. Tidal influence of salt flux is greater in winter. Gravitational circulation strengthens on moderate river flows or westerly winds.

Future efforts to understand the biogeochemical response to physical processes in estuaries and coastal lakes, requires the use of coupled hydrodynamic, water quality and ecological model combined with optimization model. And the analysis of water, salt and pollutants fluxes across a vertical cross section can done with the help of the analytical approach discussed here.
