Abstract

Phytophthora blight, caused by *Phytophthora capsici*, is a destructive disease of cucurbits and peppers in Illinois and worldwide. Fungicide use is a significant component of management strategies of *P. capsici* in cucurbits and peppers in the United States. Studies were conducted in the laboratory and field to evaluate efficacy of selected fungicides for control of *P. capsici* in pumpkin in Illinois. In the laboratory, sensitivity of five *P. capsici* isolates from Illinois was evaluated to the fungicides cyazofamid, dimethomorph, and mandipropamid. Development of colonies and production of sporangia of the isolates were assessed at concentrations of 0.0, 0.1, 0.5, 1.0, 5.0, and 10.0 µg/mL of cyazofamid, 0.0, 0.1, 0.5, 1.0, 2.5, and 5.0 µg/mL of dimethomorph; and 0.0, 0.05, 0.1, 0.5, 1.0, and 5.0 µg/mL of mandipropamid in V8 juice agar in Petri plates. In 2014, 2015, and 2017, effectiveness of the fungicides cyazofamid, dimethomorph, and mandipropamid for control of *P. capsici* in pumpkin was investigated.

In 2014, incidence of fruit rot caused by *P. capsici* was 31% in control plots and 5, 10, and 2% in the plots treated with cyazofamid, dimethomorph, and mandipropamid, respectively. In 2015, incidence of fruit rot caused by *P. capsici* was 69% in control plots and 42, 21, and 26% in the plots sprayed with cyazofamid, dimethomorph, and mandipropamid, respectively. Similarly in 2017, incidence of fruit rot caused by *P. capsici* was 48% in control plots and 7, 27, and 13% in the plots sprayed with cyazofamid, dimethomorph, and mandipropamid, respectively. In all field trials, percent vines infected with *P. capsici* in treated plots with cyazofamid, dimethomorph, and mandipropamid was significantly lower than that of control plots.

- D. Advance infection of fruit

Phytophthora blight, caused by the Oomycete *Phytophthora capsici*, has become one of the most serious threats to cucurbit and pepper production worldwide [1-5]. *P. capsici* can attack the host

plant at any growth stage causing up to 100% crop loss [3,6]. The pathogen causes seedling death, crown rot, foliar blight (Figure 1A & 1B) and fruit rot (Figure 1C & 1D) in cucurbits [3,7,8], and causes root rot, crown rot, foliar blight, and fruit rot in peppers [4,9,10]. *P. capsici* can also infect plant species in 15 families [3,11].

Phytophthora capsici is a soil-borne pathogen and produces oospores, sporangia, and zoospores. The pathogen survives between crops as oospores in soil [3,12]. Oospores are resistant to desiccation, cold temperatures, and other extreme environmental conditions, and can survive in the soil, in the absence of a host plant, for several years. Oospores germinate and produce sporangia and zoospores [2,7]. Zoospores are released in water, dispersed by irrigation or surface water, and infect plant tissues. If the environmental conditions are conducive (moist and warm), the disease develops rapidly [3,5,7,12].

The recommended management strategies for *P. capsici* in vegetables include selecting well-drained sites, planting resistant cultivars (for peppers), crop rotation, and application of fungicides [1,3,5,13]. Since there is no cucurbit resistant to *P. capsici*, use of fungicides is essential for controlling this pathogen in cucurbit crops. *P. capsici* is a multi-cycle pathogen and quickly develops resistance to fungicides. Thus, in each area, the efficacy of the fungicides for management of *P. capsici* should be assessed and the

use of fungicides should be monitored carefully. Over the past 16 years, several fungicides have been developed for management of oomycete pathogens, including *Phytophthora spp.*

Some of these fungicides are effective against *P. capsici*. Cyazofamid, dimethomorph, and mandipropamid are commonly used fungicides to manage *P. capsici* in cucurbits in Illinois and other vegetable growing areas. These fungicides have different modes of action and can be used together. This study was conducted to determine the efficacy of these fungicides for managing *P. capsici* in pumpkin production.

Materials and Methods

Phytophthora capsici isolates

Five isolates of *P. capsici* were selected from the collection maintained in Dr. Babadoost's laboratory at the University of Illinois for this study. The isolates were grown on V8-juice agar in Petri plates. V-8 juice agar was prepared by adding 50ml of V8 juice, 1.0g of CaCO₃, and 16g of agar to 950mL of distilled water.

Fungicides

Three fungicides were used in this study, including cyazofamid (FRAC code 21), dimethomorph (FRAC code 40), and mandipropamid (FRAC code 40). Commercial names of the fungicides in the United States (US) are Ranman 400 SC, Forum 4.16 SC, and Revus 2.09 SC for cyazofamid, dimethomorph, and mandipropamid, respectively.

Inhibition of mycelia growth

An *in-vitro* mycelial growth assay was conducted to determine the effective fungicide concentration at which 50% of the fungal growth was inhibited (EC₅₀) for each isolate-fungicide combination. Plugs of 7mm diameter from actively growing cultures of *P. capsici* were transferred onto V8 juice agar in Petri plates amended with technical grades of the fungicides: cyazofamid at 0.0, 0.1, 0.5, 1.0, 5.0, and 10.0µg/mL; dimethomorph at 0.0, 0.1, 0.5, 1.0, 2.5, and 5.0µg/mL; mandipropamid at 0.0, 0.05, 0.1, 0.5, 1.0, and 5.0µg/mL; and A209410D at 0, 1, 10, 50, 100, and 200µg/mL. For assays, the stock solutions of fungicides were diluted with methanol, acetone,

or water. Four plates were used for each fungicide-concentration combination. Culture plates were incubated at 25 °C in darkness. Two perpendicular diameters of colonies were measured 4 days after incubation. The experiment was repeated once under the same conditions.

Inhibition of sporangium formation

Phytophthora capsici isolates were grown on V8 juice agar in Petri plates at 25 °C in the dark for 4 days. Then, plugs of 10mm were cut from the edge of the colonies. Three 10mm² plugs were placed with the mycelium side up in a Petri plate containing sterilized distilled water (SDW) amended with fungicides cyazofamid at 0.0, 0.1, 0.5, 1.0, 5.0, and 10.0µg/mL; dimethomorph at 0.0, 0.1, 0.5, 1.0, 2.5, 5.0, and 10.0µg/mL; and mandipropamid at 0.0, 0.05, 0.1, 0.5, 1.0, 5.0, and 10.0µg/mL. The Petri plates were incubated at 25 °C under continuous light [13]. After 48 h, agar plugs with the colonies were placed on glass slides, stained and fixed with 0.01% (w/v) fuchsin acid in 85% lactic acid.

The number of sporangia was counted on two of the agar plugs using a light microscope. The fungicide concentration at which 50% of sporangia production was reduced (EC₅₀) was determined. The experiment was repeated once. Percent of suppression of sporangium formation was calculated from the ratio of the number of sporangia produced in the fungicide-amended plates to the number of sporangia in the control plates.

Field trials

In 2014, 2015 and 2017, trials were conducted in an irrigated field near Green Valley City (Tazewell County), Illinois to evaluate efficacy of selected fungicides for control of *Phytophthora* blight of pumpkin, caused by *P. capsici* (Tables 1-3). Seeds were sown on 7 May, 14 May and 15 May in 2014, 2015, and 2017, respectively. Due to continuous heavy rains in 2015, the plots were lost and the trial was re-established using 2-week old transplants on 1 August 2015. Seeds of the processing pumpkin *Cucurbita moschata* Duchesne 'Dickinson' were sown 45cm apart in single-row plots, 6m long. The plots were spaced 9m apart in a randomized complete block design with four replications.

Weeds were controlled by hand-weeding. Cucumber beetles (*Acalymma vittatum* and *Diabrotica undecimpunctata*) and other insects were managed by applying permryhrin (Pounce 25WP at 740mL/ha) and acetamiprid (Assail 30 SG at 358g/ha). Spray applications of fungicides were at 7-day intervals, as shown in (Tables 1-3). Fungicides were applied with a backpack sprayer using 469L of water per ha. The plots were irrigated as needed, using a central pivot irrigation line, which delivered 7.6ml water each time. Incidence of *Phytophthora* blight in the plots was assessed by examining 20 vines per plot prior to harvest and all of the fruit at harvest.

Results

In-vitro sensitivity of *Phytophthora capsici* to fungicides

Mycelial growth and sporangia production were significantly ($P=0.05$) reduced by all three fungicides tested in the laboratory. The EC_{50} values of the fungicides for mycelial growth ranged from 0.34 to 3.63 μ g/mL (average 1.03 μ g/mL); from 0.75 to 4.66 μ g/mL (average 2.98 μ g/mL); and from 0.13 to 7.18 μ g/mL (average 4.03 μ g/mL) for cyazofamid, dimethomorph, and mandipropamid, respectively. The EC_{50} value for sporangia production was 10, 2.5, and 0.05 μ g/mL for cyazofamid, dimethomorph, and mandipropamid, respectively.

Field trials

In 2014, vine and fruit infection was first observed in untreated plots on 1 July. Percent vines and fruits infected by *P. capsici* were significantly higher in untreated (control) plots than those in treated plots (Table 1). The lowest incidence of infected vines by *P. capsici* (6.25%) was in the plots sprayed with cyazofamid (Ranman 400F) plus Silwet L-77 alternated with mandipropamid (Revus 2.09 SC) plus Activator-90. The lowest incidence of infected fruit by *P. capsici* (4.45%) was in the plots sprayed with mandipropamid (Revus 2.09 SC) plus copper hydroxide (Kocide-3000 46.1 DF) plus Activator-90 alternated with cyazofamid (Ranman 400 F) plus Silwet L-77 alternated.

In 2015, vine and fruit infection was first observed in untreated plots on 15 September. Percent vines and fruits infected by *P. capsici* were significantly higher in untreated (control) plots than those of treated plots (Table 2). Incidence of vines infected by *P. capsici* was 5% or less in the treated, while incidence of vine infection was 10% in untreated plots. Incidence of fruit infection in treated plots ranged from 17.53 to 31.25% compared with untreated plots with 69.17% fruit infection (Table 2). Incidence of fruit infection was the lowest (17.53%) in the plots sprayed with Mandipropamid (Revus 2.09 SC) plus copper hydroxide (Kocide-3000 46.1 DF) plus Activator-90.

In 2017, vine and fruit infection was first observed in untreated plots on 15 and 28 July, respectively. Percent vines and fruits infected by *P. capsici* were significantly lower in treated plots than those of untreated (control) plots (Table 3). Incidence of vines infected by *P. capsici* was ranged from 5.00 to 23.75% in treated plots compare to 45.00% in untreated (control) plots. Incidence of fruit infection in treated plots ranged from 2.06 to 26.64% in treated plots compare

to 47.73% in untreated (control) plots (Table 3). The lowest vine infection (5%) was in the plots sprayed with mandipropamid (Revus 2.09 SC). The lowest fruit infection (2.06%) was in the plots sprayed with mandipropamid (Revus 2.09 SC) + Activator-90.

Discussion

Phytophthora blight, caused by *P. capsici*, is one of the most destructive diseases of cucurbits in the world. Management of this pathogen in cucurbits is a challenging task because no resistant cultivar of cucurbits to *P. capsici* is available. An important component of strategies for management of *P. capsici* in cucurbits is fungicide application [6]. Developed an effective seed treatment of cucurbits with mefenoxam (Apron XL LS) that prevents plant infection for five weeks from sowing seed in the soil. Over the past 16 years, several effective fungicides were developed for management of *P. capsici* in cucurbits. Among the newly developed fungicides are cyazofamid, dimethomorph, and mandipropamid.

Virulence of *P. capsici* isolates in cucurbits varies among cucurbit producing areas [3,7]. Also, *P. capsici* quickly develop resistance to fungicides [8]. Therefore, testing efficacy of fungicides for management of *P. capsici* in each cucurbit growing areas is essential. Our *in-vitro* and field tests showed that all three fungicides (cyazofamid, dimethomorph, and mandipropamid) tested are effective against *P. capsici* isolates from Illinois. But applications of these fungicides should be alternated to prevent resistance development in the pathogen. Among the three fungicides tested in fields over the past three years, mandipropamid was the most effective for management of *P. capsici* in pumpkin.

Similar results have been observed in squash and pepper trials in the fields in Illinois (Babadoost, unpublished data). Spray of mandipropamid mixed the Activator-90 and/or a copper compound (e.g., copper hydroxide (Kocide-3000 46.1 DF) is even more effective in reducing the incidence of vine and fruit infection compared to spray of mandipropamid alone. Application of mandipropamid alternated with application of cyazofamid is a reliable fungicide management of *P. capsici* in pumpkins, and likely in other cucurbits crops in Illinois.
