Introduction

Worldwide, animal products are main sources of protein, and poultry are the fastest growing sources of meat, representing nearly one fourth of all the meat produced globally. The modern production unit can produce market ready broiler chickens in about five weeks. This development arose from genetic selection, improved feeding and health management practices involving usage of antibiotics as therapeutic agents to treat bacterial diseases in intensive farming systems. They may also be used as prophylactic agents in the water of healthy chicks and as growth promoters at sub-therapeutic concentrations in feed. Bacitracin, chlortetracycline, tylosin, avoparcin, neomycin, ox tetracycline, Virginiamycin and others are used for these purposes. Sub-therapeutic dosing in feed increase the rate of weight gains and improves the efficiency of converting feed to meat. The recommended levels of antibiotics in feed were 5-10g/kg in the 1950’s and have increased by ten to twenty folds since then.

During the last 50 years antibiotics were extensively used worldwide (Figure 1 & 2) as growth enhancer to improve animal performance, fight pathogens and eliminate culling [1-10]. The Maps above shows the widespread of using antibiotics as growth promoters in animal nutrition. However, during the last two decades there were public and governmental pressures to mimic the use of AGPs in animal nutrition. Thus, as shown in Table 1, some of the members of the Organization for Economic Co-operation and Development (OECD) countries have banned the use of antibiotics as growth enhancers in animal nutrition to eliminate health hazards and sustainable agriculture and environment.

Figure 1: Antimicrobial consumption in chickens (A) and pigs (B) in 2010. Purple indicates new areas where antimicrobial consumption will exceed 30kg per 10km2 by 2030. Van Boeckel et al. [9].
Figure 2: Global antimicrobial consumption in livestock in milligrams per 10 km2 pixels (Top) and average SD of estimates of milligrams per PCU Van Boeckel et al. (9).

Phyogenic called photobiotic or botanicals, included herbs, spices and their products such as essential/violate oils and plant excretes are a group of natural growth promoters [NGPs] used as feed additives. They derived from herbs, spices or other plants to enhance livestock productivity, stimulation of appetite, improvement of digestibility by increasing endogenous digestive enzyme secretion and thus nutrient absorption, antioxidant, immune stimulant, antimicrobial and anthelmintic influences [1-10]. Phyogenic plants are good source of anti oxidants [4-6]. Additionally, they are safe for both living organisms and the environment, but the photogenic composition may vary widely due to method of processing, botanical origin, agronomical and environmental factors [7-10]. Medicinal herbs and their derivatives have many components that have anti-microbial, anti-oxidative, anti-allergic, anti-cancer, anti-mutagenic, hepato-protective, and immune-modulate, they may also enhance economic performance, to gut eco-system, production yield, food quality, and fertility [2-3].

For example, Milk thistle [Silybum marianum L. Gaert., Asteraceae] seeds and Rosemary [Rosmarinus officinalis L] leaves are new feed additives that may have promising effects. Milk Thistle has been utilized for long times by Theophrastus [4th century BC] who was possibly the first to define it under the name of “Pterix” and later it was cited by Dioskurides in his “Materiamedica” and by Plinius [1st century AD] [11-13]. Silymarin is a flavonoids mixture extracted from milk thistle seeds (MTS), which contains silybin, silydianin and silychristin; molecules that show estrogenic effect in ovariecratomized rats [14] and its major component, silibinin, bind to cytosolic estrogen receptors [15]. Milk thistles process powerful antioxidant defenses, such as those mediated by glutathione system and betaine. The MTS was utilized in Europe for many centuries for liver and gall bladder dysfunction treatments [16]. Other beneficial health components in MTS are fixed oil and anti-oxidants [16]. Silymarin is the active constituent in milk thistle seeds and represent about 4-6% of the milk thistle seed extract [17]. Other beneficial health components in MTS are fixed oil and free fatty acids and proteins, silybonol, apigenin, flavonolignans and betaine. The MTS was utilized in Europe for many centuries for liver and gall bladder dysfunction treatments [18]. The enhancing effect of silymarin is mediated through increasing endogenous antioxidant defenses, such as those mediated by glutathione system and superoxide dismutase [SOD] [19]. Silymarin is an outstanding scavenging reactive oxygen spices [ROS], antioxidant. In addition, repeated doses of extract of milk thistle extract significantly decreased biomarker [enzymes] of liver leakages while increased antioxidant enzymes of rat liver homogenate, showing free radical scavenger potential [20]. Also, lipid peroxidation controlling, thereby defending cells against oxygen species [21].

Another example of potential phyogenic with multipurpose application is the Rosemary leaves. Rosemary is rich source of antioxidant substances such as rosmarinic acid and caffeic acid [22]. Rosmarinic acid is well absorbed in the gut and from the skin, decreases the creation of leutokrine B4 in human polymorph nuclear leukocytes and prevents the complement system [23]. Furthermore, revealed that rosemary essential oil enriches rat hepatocytes’ resistance against DNA-damaging oxidative agents and effective agent for scavenging free radicals [24]. Caffeic acid and rosmarinc acid have a potential for inflammatory diseases and hepatotoxic treatments [25]. Rosemary is rich in photochemical derivatives such as triterpenes, flavonoids and apophenol. Carnosol, rosmanol and epirosmanol phenolic diterpenes of rosemary control peroxidation of unsaturated lipids [26]. Moreover, rosemary significantly decreased the elevation in peroxidiation of unsaturated lipids and boosted the levels of reduced glutahione and antioxidant enzyme actions in the kidney and testis in comparison to aspartame controls [27].

Conclusion

Research for alternative to antibiotic is an essential task in animal nutrition and can lead to replace antibiotic, safe animal products and eco-friendly environment. However, it seems that looking for complex formulas based on their active substances of different phyogenic plan and/or their products may lead to constant and better results [28]. The use of probiotics, prebiotics, symbiotic enzymes and organic acids are possible alternatives although further research is essential. The future of using phyogenic could be extended to alleviate the stressful condition and improve immunity [5,28].
