Introduction

Amputation or removal of any part is usually associated with a feeling that the missing part is still present and causes disorders of different types of sensitivity, but mainly excruciating pain sensations. The phantom pain is a false sensation, an illusion of the presence of the missing part of the body. As clinical experience shows, even with the complex application of modern anti-neuropathic agents, opioid and non-opioid analgesics, regional blocks, the treatment of phantom pain in many cases does not give positive results [1,2]. That is why it is important to search for effective methods of prophylaxis and correction of phantom pain in cancer patients. Along with medical treatment, in many countries the great attention has been recently paid to the psychotherapy. It has been proven that one of the valuable tools that can be used to reduce the intensity of pain is psychological interventions and various methods of psychotherapy, which, on the one hand, are safe, but, on the other hand, are very effective [3,4].

Purpose

Evaluation of the effectiveness of psychotherapy methods in correcting phantom pain in patients with malignant tumors of bones and soft tissues.

Material and Methods

14 patients with malignant tumors of bones and soft tissues were included in the study: bone osteosarcoma (35.7%), soft tissue sarcoma (64.3%), who underwent amputations and exarticulation of extremities in combination with lymphadenectomy aged 36 to 60 years. Clinical and psychological research provided for the use of questionnaires to assess the intensity of pain: visual analogue scale (VAS) and Wong-Baker faces pain scale. Statistical processing of the results was carried out using a package of statistical programs. The comparative analysis was carried out using Students t-test. The significance of differences in indices was P<0.05. We have chosen the methods that proved to be the simplest but at the same time, effective for reducing phantom pains: “mirror box” technique and progressive muscle relaxation. 10 sessions of “mirror therapy” (by V. Ramachandran) and 10 sessions of progressive muscular relaxation (by E. Jacobson) have been conducted with each patient, individually, in combination with music or sounds of nature. The sessions were held 2 times a day for 30 minutes of “mirror therapy” and 45 minutes of relaxation. The number of sessions was determined by the terms of the patient's hospitalization after the surgery (10-14 days).

Results and Discussion

Quantitative analysis of VAS data before and after the correction showed a significant reduction in phantom pain in the patients examined: from 73.9±9.0 to 58.9±7.9 scores, respectively (Student's t-test=4.7; P<0.05). By Wong-Baker scale, a significant decrease in the intensity of phantom pain from 7.7±1.1 to 5.7±1.1 scores (Student's t-test=5, P<0.05).

Keywords: Psychotherapy; Phantom pain; VAS; Wong-baker scale; Method of mirror therapy; Progressive muscular relaxation

Conclusion

The study showed that the proposed methods of psychotherapy using the “mirror box” and progressive muscle relaxation in
combination with music are effective in correcting phantom pain in patients with malignant tumors of bones and soft tissues.
